Conduction

**Learning Objectives**

After reading this chapter, you will know:

1. Modes of Heat Transfer, Thermal Conductivity, Thermal Diffusivity
2. One Dimensional Heat Conduction, Conduction Through Cylindrical Wall
3. Conduction Through Sphere, Thermal Resistance
4. Lumped System Method, Critical Radius of Insulation
5. Heat Transfer Through Fins, Fin Efficiency, Fin Effectiveness

**Introduction**

Conduction is the transfer of energy from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between the particles. Conduction can take place in solids, liquids or gases. Conduction is due to the collisions and diffusion of the molecules during their random motion. In solids, it is due to the combination of vibrations of the molecules in a lattice and the energy transport by free electrons.

Consider steady heat conduction through a large plane wall of thickness $\Delta x = L$ and area $A$, as shown in figure. The temperature difference across the wall is $\Delta T = T_2 - T_1$

Rate of heat conduction $\propto \frac{(Area) \,(Temperature)}{Thickness}$

Mathematically,

$$\dot{Q}_{\text{cond}} = kA \frac{T_1 - T_2}{\Delta x} = -kA \frac{\Delta T}{\Delta x}$$

Where the constant of proportionality $k$ is the thermal conductivity of the material, (differential form)

$$\dot{Q}_{\text{cond}} = -kA \frac{dT}{dx}$$
Conduction

Which is called Fourier's law of heat conduction, here \( \frac{dt}{dx} \) is the temperature gradient, which is the slope of the temperature curve on a T-x diagram (the rate of change of T with x) at location x. The relation above indicates that the rate of heat conduction in a direction is proportional to the temperature gradient in that direction. Heat is conducted in the direction of decreasing temperature.

**Thermal Conductivity**

The thermal conductivity of a material can be defined as the rate of heat transfer through a unit thickness of the material per unit area per unit temperature difference. The thermal conductivity of a material is a measure of the ability of the material to conduct heat.

In SI unit of thermal conductivity is W/mK

**Thermal Diffusivity**

Material property that appears in the transient heat conduction analysis is the thermal diffusivity. Which represents how fast heat diffuses through a material and is defined as,

\[
\alpha = \frac{\text{Heat conducted}}{\text{Heat stored}} = \frac{k}{\rho C_p}
\]

**Note:** That the thermal conductivity, \( k \) represents how well a material conducts heat and the heat capacity, \( \rho C_p \) represents how much energy a material stores per unit volume. Therefore, the thermal diffusivity of a material can be viewed as the ratio of the heat conducted through the material to the heat stored per unit volume. A material that has a high thermal conductivity or a low heat capacity will obviously have a large thermal diffusivity. The larger the thermal diffusivity, the faster the propagation of heat into the medium.

In SI unit of thermal diffusivity is \( \text{m}^2/\text{s} \)

**One Dimensional Heat Conduction**

Heat transfer has direction as well as magnitude. The rate of heat conduction in a specified direction is proportional to the temperature gradient, which is the change in temperature per unit length in that direction. Heat conduction in a medium, in general, is three-dimensional and time dependent. That is, \( T = T(x, y, z, t) \) and the temperature in a medium varies with position as well as time. Heat conduction in a medium is said to be steady when the temperature does not vary with time and unsteady or transient when it does. Heat conduction in a medium is said to be one-dimensional when conduction is significant in one direction only and negligible in the other two dimensions, the governing differential equation in such systems in rectangular, cylindrical and spherical coordinate systems is derived in below section.

**Rectangular Co-ordinates**

Consider a small rectangular element of length \( \Delta x \), width \( \Delta y \) and height \( \Delta z \), as shown in figure. Assume the density of the body is \( \rho \) and the specific heat is \( C \), an energy balance on this element during a small time interval \( \Delta t \) can be expressed as
Three-Dimensional Heat Conduction Through a Rectangular Volume Element

\[
\begin{bmatrix}
\text{Rate of heat conduction at } x, y \text{ and } z \\
\end{bmatrix} = \begin{bmatrix}
\text{Rate of heat conduction at } x + \Delta x, y + \Delta y, z + \Delta z \\
\end{bmatrix} + \begin{bmatrix}
\text{Rate of heat generation inside the element} \\
\end{bmatrix} - \begin{bmatrix}
\text{Rate of change of the energy content of the element} \\
\end{bmatrix}
\]

Noting that the volume of the element is \( V_{\text{Element}} = \Delta x \Delta y \Delta z \), the change in the energy content of the element and the rate of heat generation within the element can be expressed as

\[
\frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + \dot{g} = \rho C \times \frac{\partial T}{\partial t}
\]

Since, from the definition of the derivative and Fourier’s law of heat conduction.

\[
\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} + \frac{\dot{g}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t}
\]

1. Steady-State: (Poisson’s equation)

\[
\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} + \frac{\dot{g}}{k} = 0
\]

2. Transient, no heat generation: (Diffusion equation)

\[
\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}
\]

3. Steady state, no heat generation: (Laplace equation)

\[
\nabla^2 T = 0
\]
**Cylindrical Co-ordinates**

\[ x = r \cos \phi, \quad y = r \sin \phi \quad \text{and} \quad z = z \]

A differential Volume Element in Cylindrical Co-ordinates

After lengthy manipulations we obtain

\[ \frac{1}{r} \frac{\partial}{\partial r} \left( kr \frac{\partial T}{\partial r} \right) + \frac{1}{r^2} \frac{\partial}{\partial \phi} \left( kr \frac{\partial T}{\partial \phi} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + \dot{g} = \rho C_\text{M} \frac{\partial T}{\partial t} \]

**Spherical Co-ordinates**

\[ x = r \cos \phi \sin \theta, \quad y = r \sin \phi \sin \theta, \quad \text{and} \quad z = \cos \theta \]

A Differential Volume Element in Spherical Co-ordinates

Again after lengthy manipulations, we obtain

\[ \frac{1}{r} \frac{\partial}{\partial r} \left( kr^2 \frac{\partial T}{\partial r} \right) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \phi} \left( k \frac{\partial T}{\partial \phi} \right) + \frac{\partial}{\partial \theta} \left( k \sin \theta \frac{\partial T}{\partial \theta} \right) + \dot{g} = \rho C_\text{M} \frac{\partial T}{\partial t} \]

**Conduction Through a Cylindrical Wall**

For a cylinder at steady state, with no internal heat generation, the equation becomes

\[ \frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} = 0 \Rightarrow \left( \frac{1}{r} \right) \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = 0 \quad \text{and} \quad K = \text{constant} \]

B.C \rightarrow Boundary conditional

On integration and substituting the B.C’s, we get the temperature distribution equation as
Conduction

\[
\frac{T - T_1}{T_2 - T_1} = \frac{\log(r/r_1)}{\log(r_2/r_1)}
\]

\[
Q = \frac{(T_1 - T_2)}{R_1} \text{ where, } R_1 = \frac{\log(r_2/r_1)}{2\pi kL}
\]

Comparing the above equation to that of heat transfer through a wall:

\[
Q = \frac{kA (T_1 - T_2)}{\delta} = kA_m (T_1 - T_2)/(r_2 - r_1)
\]

Where, \(A_m\) is the logarithmic mean area = \((A_2 - A_1)/\log (A_2/A_1)\)

Conduction Through Sphere

Steady state, one dimensional with no heat generation equation in spherical co-ordinates is

\[
\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = 0
\]

On integration and substituting the B.C’s we get the temperature distribution equation as,

\[
\frac{T - T_1}{T_1 - T_2} = \frac{r_2}{r} \left[ \frac{r - r_1}{r_2 - r_1} \right]
\]

From the above, it is seen that it is hyperbolic

Heat Transfer rate = \(Q = \frac{(T_1 - T_2) 4\pi kr_1 r_2}{(r_2 - r_1)} = \frac{[T_1 - T_2]}{R_t}\)

Where, \(R_t = (r_2 - r_1)/4\pi k r_m^2\)

Comparing the above equation to that of heat transfer through a wall.

\[
Q = \frac{(kA \Delta T)}{\delta} = \frac{(k A_m \Delta T)}{(r_2 - r_1)}
\]

Where, \(A_m = 4\pi r_1 r_2 = 4\pi r_m^2\)

\[
r_m = \sqrt{r_1 r_2}
\]

Thermal Resistance

In particular, there exists an analogy between the diffusion of heat and electrical charge. Just as an electrical resistance is associated with the conduction of electricity, a thermal resistance may be associated with the conduction of heat.

\[
R_{t,\text{cond}} = \frac{T_{s1} - T_{s2}}{q_x} = \frac{L}{kA}
\]
Similarly, for electrical conduction in the same system, Ohm’s law provides an electrical resistance of the form

\[ R_e = \frac{E_{s1} - E_{s2}}{1} = \frac{L}{\sigma A} \]

The analogy between above equations is obvious. A thermal resistance may also be associated with heat transfer by convection at a surface. From Newton’s law of cooling,

\[ q = hA \left( T_s - T_\infty \right) \]

The thermal resistance for convection is then

\[ R_{\text{total,conv}} = \frac{T_s - T_\infty}{q} = \frac{1}{hA} \]

Circuit representations provide a useful tool for both conceptualizing and quantifying heat transfer problems. The equivalent thermal circuit for the plane wall with convection surface conditions is shown in figure.

\[ Q_x = \frac{T_{\infty 1} - T_{s1}}{1/h_1A} = \frac{T_{s1} - T_{s2}}{L/h_1A} = \frac{T_{s2} - T_{\infty 2}}{1/h_2A} \]

In terms of the overall temperature difference, \( T_{\infty 1} - T_{\infty 2} \) and the total thermal resistance, \( R_{\text{total}} \), the heat transfer rate may also be expressed as,

\[ Q_x = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{Total}}} \]

Because the conduction and convection resistances are in series and may be summed, it follows that

\[ R_{\text{total}} = \frac{1}{h_1A} + \frac{L}{kA} + \frac{1}{h_2A} \]

Radiation exchange between the surface and surroundings may also be important if the convection heat transfer coefficient is small (as it often is for a natural convection in a gas). A thermal resistance for radiation may be defined by

\[ R_{\text{total,rad}} = \frac{T_s - T_{\text{sur}}}{q_{\text{rad}}} \]
